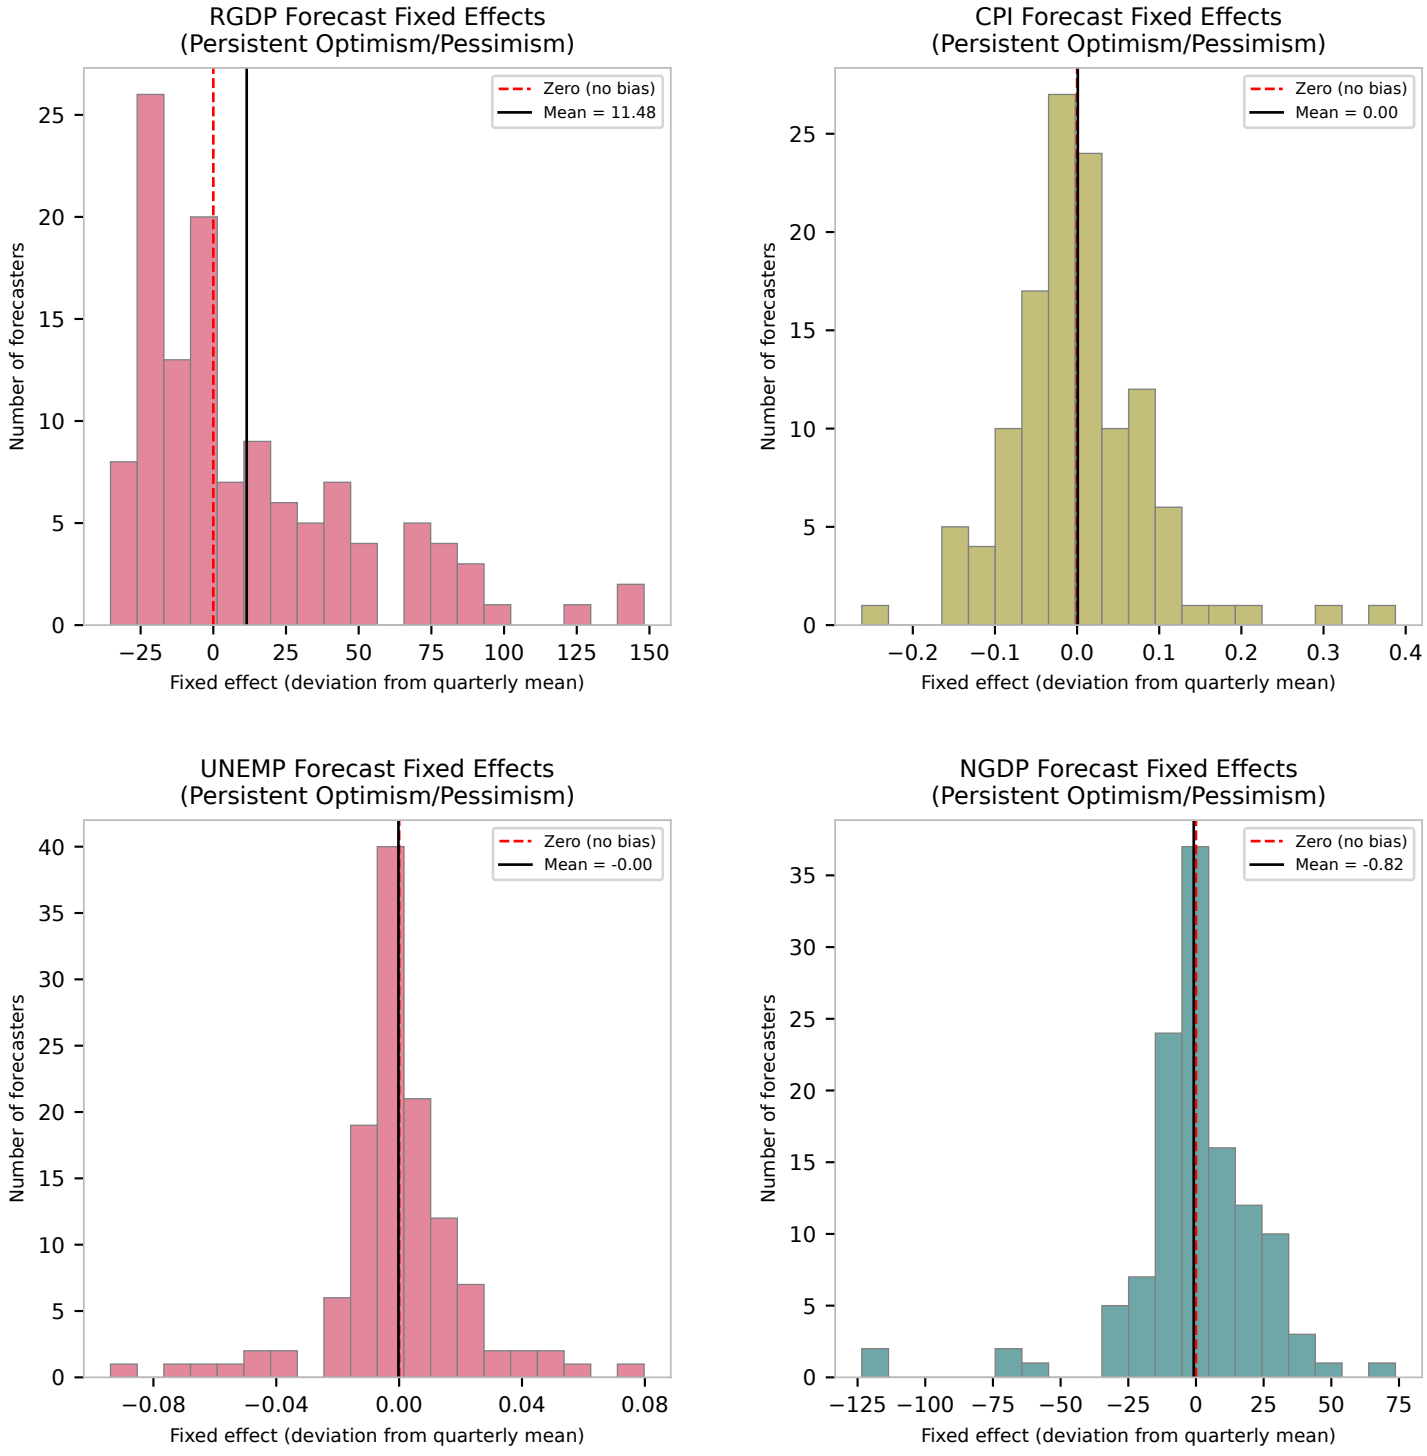
Figure 4. Distribution of forecaster fixed effects

Reconstructed from raw AI nowcasts: retain forecasters with at least ten valid observations, then subtract quarterly cross-sectional means and average each forecaster's deviations.



Recovered calculation matches the published histogram means and shapes. Actual retained sample: 121 forecasters; the caption's 194 is the count before the ten-observation restriction. Horizon and restriction order were omitted from the paper; both are documented here.
